ABSTRACT

The use of renewable energy sources is highly demand in electricity market nowadays. The incorporation of renewable energy sources with the utility grid has becoming a challenging task in power system as it arises several control issues such as grid stability, power quality control, loads sharing and others. This paper presents current control methods namely Hysteresis controller and Proportional-Integral controller used to interface of single-phase grid connected inverter with nonlinear load. The impact of nonlinear load on grid current is analysed by measuring the performance of total current harmonics distortion (THD) level in MATLAB™ Simulink software environment.

Key words: THD, harmonics, hysteresis current control, power quality, Proportional-Integral, Renewable energy sources

1. INTRODUCTION

Nowadays, variety of renewable energy applications which includes solar energy, wind energy, hydro, geothermal, tidal and wave energy had been implemented in distributed generation system. Due to the rapid development of renewable energy technologies, it has steered to the production of low cost renewable power generation. RES are highly demand due to its many advantages such as high sustainability, economic profits and able to provide clean energy which makes it environmental-friendly [1-3].

The integration of renewable energy based on power plant into distributed system leads to the rise of power electronic converters’ usage. The power generated by renewable energy sources based distributed generation is transformed by converter into the form of power that is reconcilable with distributed grid. However, the power exchange between DG and the grid raises several control issues. One of the challenging issues is power quality control. The presence of harmonics due to combination between VSI and DC with grid or nonlinear loads causes voltage and current signals to be distorted and injected into the grid by DG inverter [4-8].

Various current control strategies had been proposed by researchers to compensate harmonics content in output waveform of inverter. The most significant current control strategies include PI control, predictive current controller, state feedback controller, ramp time current controller and hysteresis controller [9-12]. The application of PI controller can be seen in single phase inverter connected to grid [13-15].

Inverter and non-linear load generate unwanted harmonics distortion which cause reduction in power quality. Good quality current injected into the grid can also be achieved through modified PI controller by eliminating the steady state error in closed-loop system [16]. Hysteresis controller is another type of current controller that is commonly applied in control system application due to its directness and fast response. One of the disadvantages of hysteresis controller is that it has high switching frequency which leads to undesirable harmonics. A modified hysteresis controller is presented to reduce switching losses in grid-connected inverter system [17-19]. The proposed hysteresis controller is proven to have the ability to minimise switching losses without sacrificing output current waveform.

This paper aims to assess the control performance of three current control techniques, which are hysteresis, PI and combination of hysteresis with PI controller. A single-phase grid connected inverter with nonlinear load act as the testing platform of the project. The results which indicates the behavior of each current control techniques being tested under controlled condition are analysed and compared.

2. SINGLE-PHASE GRID CONNECTED INVERTER SETUP

There are three major components needed in single-phase grid connected inverter; the inverter, the grid and the load. By referring to Figure 1, DC voltage supply is used to supply voltage to be fed to the voltage source inverter. VSI converts DC to AC voltage to be delivered into the utility grid. RLC filter helps to filter out switching harmonics of Pulse Width Modulation (PWM).
Switching capacitor, $C_{\text{switching}}$ removes the switching components on point-of-common-coupling (PCC) from entering the grid while inverter inductance allows ripples in source current. Grid inductance, $L_{\text{grid}}$ exists as the grid impedance and non-linear load draws distorted harmonics current into the grid. Hysteresis controller and PI controller compensate the harmonics content in the grid current. Bipolar PWM is generated through the PWM technique to be fed into the inverter.

For synchronization between the inverter and the grid, this project does not require Phase-Locked-Loop (PLL) method. This is because the reference voltage is directly taken from the grid voltage whereas the reference current is taken from the output current of inverter. Through this method, it is more robust and constructive compared to conventional reference signal generation as this method can minimize cost and lessen the number of components such as PLL. Note that the desired voltage waveform must be obtained first in order to control the current waveform.

Table 1 below synopses the parameters used in the system.

3. CURRENT CONTROL TECHNIQUES

There are three current control methods being compared in this paper. The main reason of choosing hysteresis controller and PI controller is due to their simplicity and easily understood.

3.1 Hysteresis Current Control

Since hysteresis current control is simple and easy to be implemented, it is widely used in grid-connected inverters mode. The operation of this control system works by comparing the measured output current of the single phase inverter with the reference current. As the controller produces switching pulses for the IGBTs, a fixed hysteresis bandwidth which consists of upper limit and lower limit is used to control the error of current within its range. The switches S1 and S4 are at ON state when the current error reaches the upper limit while S2 and S3 are turned ON if the current error meets the lower limit. Figure 2 and Figure 3 below show the hysteresis controller block diagram and switching pattern of hysteresis current control waveform.

![Figure 1: Overall system configuration of single-phase grid connected inverter with nonlinear load.](image1)

![Figure 2: Hysteresis controller block diagram [19]](image2)

![Figure 3: Switching pattern of hysteresis current control [19]](image3)
In order to achieve desired reference current tracking, the hysteresis bandwidth, \( h \) can be determined by this equation:

\[
h = \frac{(V_{dc}^2-V_{grid}^2)}{4V_{dc}L_{fs}}
\]  

(1)

The current error is controlled by calculating the switching frequency of the inverter connected to grid. The switching cycle is expressed by \( 0 \rightarrow t_1 \) period, where:

\[
t_1 = \frac{T_{on} \times 2L_{HB}}{V_{dc} - V_{grid}}
\]  

(2)

For \( t_1 \rightarrow T \) period, the equation can be computed as:

\[
T - t_1 = T_{off} = \frac{2L_{HB}}{V_{dc} + V_{grid}}
\]  

(3)

The simulation modelling of hysteresis controller is shown in Figure 4 below. The generation of \( I_{ref} \) is taken from the output current from inverter whereas the measured current is referred to output current from grid, \( I_{grid} \). The error between both reference and measured current are controlled in a region containing upper and lower limit called hysteresis band.

3.2 Proportional-Integral Controller

Proportional Integral (PI) controller is the most ordinary and widely used controller due to its simplicity and better stability in control system. P controller adds integral component in transfer function to eliminate steady state error. The expression for PI controller is equal to:

\[
\text{Pl}(s) = K_p + \frac{K_i}{s}
\]  

Where \( K_p \) tends to reduce the error between reference current and measured current while \( K_i \) controls the oscillation of the system. The reference current that came out from the PI controller will enter the hysteresis band in order to regulate its error within certain range. The output current from inverter can be given as:

\[
I_o = i_{ref} + e
\]  

(6)

Thus, deviation of error can be written as:

\[
\frac{de}{dt} = \frac{V_{dc} - V_{grid}}{L_f}
\]  

(7)

As IGBT switch 1 and 4 is ON, the error of current changes...
from negative HB to positive HB. The ON time interval can be calculated as:

\[ T_{ON} = \frac{2LfHB}{V_{dce}-V_{grid}} \]  

(8)

When IGBT switch 2 and 3 is ON, similar method can be applied where the equation is given as:

\[ T_{ON} = \frac{2LfHB}{V_{dce}+V_{grid}} \]  

(9)

By combining equation (8) and (9), the switching frequency of the system is:

\[ f_s = \frac{(V_{dce}-V_{grid})}{4V_{ac}fHB} \]  

(10)

The overall Simulink block design of PI with hysteresis current controller is demonstrated in Figure 8 below.

4. PERFORMANCE MEASURES

In this paper, the evaluations of the current control techniques are analysed through First Fourier Transform (FFT) analysis. Through the analysis, it gives insight about the dynamic performance of the current control techniques. Harmonics content in a current waveform is measured through Total Current Harmonics Distortion (THD\(i\)).

It can be expressed as the summation of all harmonics component of the current waveform against the fundamental frequency of current as shown in equation (11).

This means that the output of a system receives the same fundamental frequency as the input when a sinusoidal input is applied with nonlinear system. Higher percentage of THD\(i\) indicates that more distortions are present in the waveform.

\[ THD_i = \frac{1}{I_{fundamental}} \sqrt{\sum_{n=2}^{\infty} I_{resultant,n}^2 \times 100\%} \]  

(11)

Every project should comply with a benchmark set by certain standards. In this project, the standard for current harmonics distortion used is IEEE 519-2014 [21] which stated that THD\(i\) must below than 5%.

5. RESULTS & DISCUSSIONS

Table 2: THD\(i\) values of I\textsubscript{grid} without and with current controllers

Figure 9: Harmonics spectrum of I\textsubscript{grid} given by all three current controllers

From the THD\(i\) values obtained which are presented in Table 2, PI controller is observed to deliver the highest distortion due to its slow response, resulting in non-zero steady state error. Hysteresis controller shows better total harmonic distortion than PI controller due to its fast response current loop but have low order harmonics and variation in switching frequency. The combination of PI with hysteresis current controller makes the system more robust. Figure 9 shows the lower order harmonics spectrum of I\textsubscript{grid} of all three current control methods. The fundamental component is excluded in order to highlight the harmonic content. Hysteresis current controller displayed the highest harmonic content from 5\textsuperscript{th} order to 19\textsuperscript{th} order of harmonics. This is because hysteresis current controller allows the current to flow freely within its hysteresis band, resulting in lower order harmonics.
Apart from that, variation in switching frequency of hysteresis current controller also contributes to this factor. The higher order harmonics is absent in the harmonic spectrum. This is because there are inductance being used in the circuit of project. Inductance is represented as $R + j \omega L$, where $\omega$ is equal to $2\pi f$. The inductance is directly proportional to the frequency. When impedance is high, the order of harmonics also increases, resulting in lesser magnitude as compared to lower order harmonics. This is why filters are used to block the higher order harmonics.

Table 3 summarise the overall performance of all three controllers in terms of $V_{\text{inv}}$, $I_{\text{grid}}$, and THD of $I_{\text{grid}}$.

<td>THD = 5.53%</td>
</tr>
</tbody>
</table>

In this paper, the simulation study of single phase grid-connected inverter with PI, hysteresis and combination of PI with hysteresis controller has been presented. From the simulation results, it is proven that hysteresis controller exhibits the best and fast current control response, followed by 5.53% of PI with hysteresis current controller and 5.68% of PI controller. Although hysteresis current controller have variation in switching frequency, it has fast current response which displays a good dynamic performance. PI controller unable to generate the lowest THD level of $I_{\text{grid}}$ because it has several drawbacks such as slow dynamic response and non-zero steady state error. When both controllers are combined together, the system is considered to be more stable and reliable enough to mitigate any sorts of harmonic content in signals.

6. CONCLUSION

In this paper, the simulation study of single phase grid-connected inverter with PI, hysteresis and combination of PI with hysteresis controller has been presented. From the simulation results, it is proven that hysteresis controller exhibits the best and fast current control response, followed by combination PI with hysteresis controller which makes the system sturdier and PI controller as the third best due to its inability to inherit zero steady state error. All current
controllers proposed in this paper managed to improve the waveform quality without affecting the output voltage of inverter by eliminating the impact of nonlinear load on the grid current.
