

STUDY ON CHARACTERISTICS OF  
SEDIMENT AND SEDIMENTATION RATE IN  
KENAU RIVER FOR YEAR 2008, 2016 AND  
2019

ABDUL RAHMAN BIN ALIMUDDIN

UNIVERSITI MALAYSIA PAHANG

## **STUDENT'S DECLARATION**

I hereby declare that the work in this thesis is based on my original work except for quotations and citations which have been duly acknowledged. I also declare that it has not been previously or concurrently submitted for any other degree at Universiti Malaysia Pahang or any other institutions.

---

(Student's Signature)

Full Name : ABDUL RAHMAN BIN ALIMUDDIN

ID Number : AA15222

Date : 30 MAY 2019

STUDY ON CHARACTERISTICS OF SEDIMENT AND SEDIMENTATION RATE  
IN KENAU RIVER FOR YEAR 2008, 2016 AND 2019

ABDUL RAHMAN BIN ALIMUDDIN

Thesis submitted in fulfillment of the requirements  
for the award of the  
B. Eng (Hons) Civil Engineering

Faculty of Civil Engineering and Earth Resources  
UNIVERSITI MALAYSIA PAHANG

MAY 2019

## ACKNOWLEDGEMENTS

By the name of Allah, Most Gracious, Most merciful. Praise to Him the Almighty that in His will and given strength to me for completing my progress report. Praised to Prophet Muhammad S.A.W his companions and to those who on path as what he preached upon, may Allah Almighty keep us to His blessing and tenders.

On the completion of this thesis with the title ‘ Study on Characteristics of Sediment and Sedimentation Rate in Kenau River for Year 2008, 2016 and 2019’. I would like to present my highest gratitude to Allah S.W.T for His love and mercy.

I would like to express my high appreciation to my supervisor, Madam Nadiatul Adilah Binti Ahmad Abdul Ghani who is really supportive in advising me in completing my research study. Madam Nadiatul has successfully guiding, facilitating, motivate and support during my hard moment in completing this research work.

I also want to thank my friend, Muhammad Zarif Bin Md Uzairin, Muhammad Taufik Bin Suhaimi and Basri Bin Abdul for their help in assisting me completing my work in collecting data and also the laboratory work.

I am also very thankful to the technicians of Hydraulics and Hydrology Laboratory and Concrete Laboratory especially Madam Kamariah and Mr Syed for their help during my research.

Lastly, I would like to thank my family for giving me spiritual support and greatest caring along the way to complete this study.

## ABSTRAK

Kajian ini dijalankan di Sungai Kenau, Sungai Lembing, Kuantan. Objektif kajian ini dijalankan adalah untuk menentukan perubahan ciri-ciri sedimen di Sungai Kenau dari tahun 2008 ke 2019. Ujian makmal telah dilakukan untuk mengenalpasti perubahan sifat-sifat sedimen melibatkan saiz, ketumpatan dan halaju sedimen. Pengagihan saiz zarah telah dijalankan untuk mengklasifikasikan sifat-sifat sampel tanah. Berpandukan ujian klasifikasi tanah, tanah di kawasan ini dikenalpasti sebagai tanah kerikil iaitu tanah dan lumpur halus. Objektif kedua adalah untuk menentukan persamaan terbaik untuk meramal sedimen di Sungai Kenau. Keratan rentas tasik telah diukur dan dibandingkan untuk melengkapkan objektif kajian. Sungai Kenau telah mengalami banyak perubahan sepanjang tempoh 11 tahun. Ciri-ciri di Sungai Kenau diperlukan untuk mengenal pasti kerana ia boleh menjejaskan aliran sungai semasa hari biasa dan peristiwa banjir. Kajian yang dijalankan melibatkan lima lokasi kajian yang berbeza. Hasil ujian pengamatan sampel sedimen diklasifikasikan menggunakan Sistem Klasifikasi Tanah Bersepadu (USCS). Klasifikasi tanah di Sungai Kenau diklasifikasikan sebagai Pasir Gred Rendah (SP). Data kadar alir air direkodkan menggunakan meter arus berkipas. Kadar aliran tertinggi dicatatkan kira-kira 2.940 m<sup>3</sup>/s terletak di Stesen 2. Kadar aliran terendah yang direkodkan adalah kira-kira 1.523 m<sup>3</sup>/s yang terletak di Stesen 4. Persamaan terbaik untuk digunakan bagi menentukan kadar sedimen di Sungai Kenau ialah persamaan Ackers-White untuk pengangkutan sedimen.

## ABSTRACT

This study was conducted at Kenau River at Sungai Lembing, Kuantan. The objective of the study is to determine the changes of sediment characteristics at Kenau River from year 2008 to year 2019. In order to determine the change of sediment properties regarding size, density and fall velocity, several related were conducted in the laboratory. Particle size distribution was carried out to classify properties of the soil sample. From the soil classification test, this soil is gravel soil with fine soil and silt. The second objective is to determine the best equation to predict the sediment at Kenau River. The cross section of river had measure and compare. It overcome huge changes after 11 years. The characteristics at Kenau River required to identify because it may affect the flow of the river during a usual day and flood event. This study involves five location of study area. The sediment sample sieving test results was classified using Unified Soil Classification System (USCS). The soil classification at Kenau River for every station is almost entirely classified as Poorly Graded Sands (SP). The flow rate data also had record for every location by using current mer. The highest flow rate was recorded about 2.940 m<sup>3</sup>/s located at Station 2. The lowest flow rate recorded is about 1.523 m<sup>3</sup>/s located at Station 4. The best equation to be used to determine sediment rate at Kenau River is Ackers-White equation for sediment transport.

## CHAPTER 1

### INTRODUCTION

#### 1.1 Introduction

Sediments are the fragments of rocks and minerals that comes from the weathering of rock and are carried and deposited by wind, water or ice. When the rainfall occur, the materials are dislodged and transported on the land surfaces. Rivers and streams will act as a passage for the movement of sediments and deposition will occur when there is no enough energy to transport the sediments. These passages will carry the sediment as they flow depending on the sediment supply along their course.

Water is the main transportation types for sedimentation which called as fluvial processes. Besides water, wind or Aeolian processes also one of the types of transportation for the sedimentation process. Sedimentation is accomplished when the velocity of the water treated is decreased under condition which the particles will no longer remain suspension.

The sedimentation rate is the process to design of classifier which also used to separate solids by their size and density under free and hindered settling condition. The total sedimentation rates are estimated annually along established by direct survey of the river bottom.

Sediment transport or sediment load deals with the interrelationship between flowing water and sediment particles, which means the material in suspension and or in transport. Typically, the greater the flow, the more sediment will be transported. During transport in water body, the total sediment load are divided into two categories, which are wash load and bed-material load. While in term of movement, the sediment can be identified as bed load transport and suspended load. The several factors affecting the

sediment transport are velocity, depth of flow, particle sediment size, geometry cross section and course of river flow.

Once the sediment has entered waterways, it is difficult and expensive tasks to remove where engineering solutions and heavy equipment are required. A question on how much sediment would be carried by a river under a given hydraulic condition makes the study of sediment transport is one of great engineering importance using the suitable methods or functions.

## **1.2 Background of Study**

Sediment movement is a natural part of a functioning freshwater ecosystem, human activities around waterways such as dam or road construction or land use change from native forest to pasture can greatly increase the amount of sediment that enters the system. This situation can have considerable effects on water quality; plant and animal live there, and water level. The addition of sediment to rivers and streams above normal levels is a serious issue. This means, the study of sedimentation rate is quite important since the problem related to our human society such as floods and water quality can be avoided. For example, the depth of river become shallow if the sedimentation occurred. It will make the quantity of aquatic life will reduced and the area will face flooding because the river become overflow due to sedimentation process.

At the same time, when the sediments in river system are high and it is still behind a dam, the sediments will sink to the bottom of the reservoir. This situation refers to reservoir sedimentation. Then, as the sediment are accumulated in the reservoir, the dam will rapidly reduce its usefulness or lifespan to store water. This accumulation of sediment in reservoirs may have several effects such as reduce the useful storage volume, change water quality, increase flooding level upstream and influence stability of the stream at downstream of dam.

Sediment transport is important in the field of sedimentary geology, geomorphology, civil engineering and environmental engineering. It is movement of solid particles, typically due to a combination of gravity acting on the sediment, and/or

the movement of the fluid in which the sediment are entrained. Knowledge of sediment transport is most often used to determine whether erosion or deposition will occur, the magnitude of this erosion or deposition, and the distance over which it will occur.

Total sediments transport in streams or rivers is categorized into bed load, which are transported near or along the bed by rolling, bounding and sliding, and suspended load, which are carried in suspension through water column. The total sediment transport processes in a river system are varies across river catchment which depends on the interaction among sediment size, discharge energy, channel bed conditions and channel obstructions. There are several equations or functions, which have been developed for estimating sediment, transport in an alluvial channel. However, because of the sediment transport, processes are sensitive to a number of variables representing the strength of the flow, the fluid and the sediments; so that the sediment transport potential can be, vary by an order of magnitude depending on the similarity of material and hydraulic parameters between the rivers and developed functions.

The sediments are basically fragments of rock and minerals that come from the weathering of rock. When the rain falls, materials are dislodged and these materials are transported on the land surface, streams and rivers act as passage for the movement of sediments. When there is not enough energy to transport the sediments, deposition occurs. Rivers and streams carry sediment supply as they flow depending on the sediment supply along their course. Depending on settling velocity, drag and lift force, these sediment are carried along the river in either suspended form or bed load. At the same time, these factors are broadly classified in affecting sediment transport such as hydrology and climate, topography, geology and land use.

The transportation of sediment depends not only on the characteristics of the flow involved, but also on the properties of the sediment itself. Those properties of most importance in the sedimentation processes can be divided into properties of the particles and of the sediment as a whole. The most important property of the sediment particle or grain is its size. In most of the river sediment studies, average size alone has been used to describe the sediment as a whole. To obtain more accurate results, a more precise description of sediment is required.
