ABSTRACT

Nanocrystals of a new complex perovskites ceramic oxide, barium thulium antimony oxide – Ba_2TmSbO_6 , were synthesized using a single step auto-ignition combustion process. The combustion product was single phase and composed of aggregates of nanocrystals of sizes in the range 20–50 nm. Ba_2TmSbO_6 crystallized in cubic perovskite structure with lattice parameter, a=8.4101 Å. The polycrystalline fluffy combustion product was sintered to high density ($\sim97\%$) at $\sim1450\,^{\circ}\text{C}$ for 4 h. Resistivity of the sintered specimen was $\sim5\,\text{M}\Omega/\text{cm}$. The Ba_2TmSbO_6 has dielectric constant (ϵ') and dielectric loss ($\tan\delta$) of 17 and $\sim10^{-4}$ at 5 MHz; the new material would probably be developed as a low-loss dielectric material.

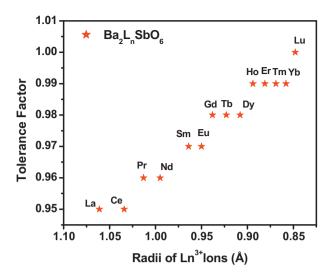

Fig. 1. Tolerance factor of $Ba_2L_nSbO_6$ as a function of ionic radii of lanthanides. All the ionic radii were obtained from Shannon and Prewitt. The R_B was obtained from the average of radii of L_n and Sb.

To the best of our knowledge, little study was undertaken either on crystal structure or on dielectric properties for $Ba_2L_nSbO_6$ that employs an L_n of lower ionic radii such as Tm. We have now synthesized Ba_2TmSbO_6 ($R_{Tm} < R_{Ho}$) as nanocrystals using a solution combustion method [14] and studied its crystal structure and dielectric properties. Synthesis of advanced and specialty materials as nanocrystals through wet chemical processes is recently a topic of intense research interest due to their characteristics such as superior phase purity, homogeneity, and sinterability which lead to compact solids with superior physical properties [15]. The Ba_2TmSbO_6 thus synthesized have cubic ($Fm\bar{3}m$) crystal structure as predicted by Fig. 1 and showed the lowest dielectric loss ($tan \delta$) so far reported for any $Ba_2L_nSbO_6$.

2. Experimental details

An aqueous solution containing ions of Tm, Ba, and Sb was prepared from high purity Tm₂O₃ (99.9%, Alfa Aesar, USA), Ba(NO₃)₂ (99.9%, CDH, India) and Sb₂O₃ (99.9%, Merck, USA) using the procedure described elsewhere [14-18]. The Tm₂O₃ and Sb₂O₃ were dissolved in nitric and tartaric acids, respectively. Citric acid was added to the solution containing the metal ions, maintaining the citric acid to the cation ratio at unity, to get a precursor complex. The oxidant fuel ratio of the system was adjusted by using nitric acid and ammonium hydroxide, and the ratio was kept at unity. The solution containing the complex precursor mixture at a pH of \sim 7.0 was heated using a hot plate at \sim 250 °C in a ventilated fumehood. The solution boils on heating and undergoes dehydration and decomposition leading to a smooth deflation and foams. The foam then ignites by itself on persistent heating giving voluminous and fluffy product of combustion. The as-prepared Ba₂TmSbO₆ were mixed with 5% polyvinyl alcohol, dried, and pressed in the form of cylindrical pellet of \sim 14 mm diameter and \sim 2 mm thickness at a pressure ~350 MPa. The pellets were then sintered at 1450 °C for 4 h.

Crystal structure of the as-prepared powder and the sintered product were examined by powder X-ray diffraction (XRD) technique using X-ray diffractometer (Model Bruker D-8) with Nickel filtered Cu K α radiation. The differential thermal (DTA) and thermo gravimetric analyses (TGA) of the combustion product were carried out using Perkin-Elmer TG/DT thermal analyzer in the range $30-1000\,^{\circ}\text{C}$ at a heating rate of $20\,^{\circ}\text{C}/\text{min}$ in nitrogen atmosphere. The infrared (IR) spectra of the samples were recorded in the range

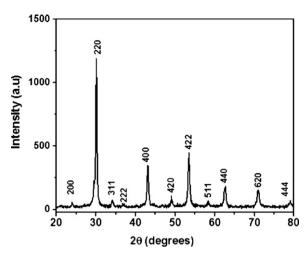

Fig. 2. XRD pattern of as-prepared Ba_2TmSbO_6 indexed to the (hkl) $Fm\bar{3}m$ space group.

400-4000 cm⁻¹ on Thermo-Nicolet Avatar 370 Fourier Transform Infrared (FT-IR) spectrometer using KBr pellet method. Particulate properties of the combustion product were examined using scanning electron microscopy (SEM; Quanta 200 FEG System: FEI Company, USA) and transmission electron microscopy (TEM, Model-Hitachi H-600 Japan, 200 kV). Theoretical density of the Ba₂TmSbO₆ was calculated from the lattice constants and sintered density was measured following the Archimedes method. The surface morphology of the sintered samples was examined using SEM (Model-Hitachi S 2400, Japan). Crystal structure of the sintered material was studied by the Rietveld analysis of XRD measurements. PowderCell 2.3 program was used to fit the observed XRD patterns. For dielectric measurements, silver electrodes were attached on either sides of the sintered pellet and dried at 80 °C for 15 min. The capacitance measurements were carried out using an LCR meter (HIOKI 3532-50) in the 50 Hz to 5 MHz frequency range.

3. Results and discussion

3.1. Powder characteristics and sintering of Ba₂TmSbO₆

The solution combustion process employing citric acid with the help of the ammonium hydroxide and nitrate ions [14] is currently the only available technique that synthesizes nanocrystalline metal oxides in a single step process. Usually powders obtained directly after combustion using this process are single phase; any further heating procedure only results in grain growth. Fig. 2 shows the XRD pattern of the as-prepared sample. No secondary or unreacted components were detected in the XRD patterns. All peaks in the XRD pattern were indexed for a cubic perovskite structure in Fig. 1. Lattice parameter calculated from the XRD pattern was $a = 8.409 \,\text{Å}$. Size of the crystallites calculated from the width of the XRD pattern was \sim 20 nm. Fig. 3 shows DTA and TGA curves of the powders after the combustion synthesis. The TGA curve did not show any appreciable weight change up to 1000 °C indicating that the combustion is complete and there are no nitrates or carbonates; and therefore, the product is pure oxide. This observation was supported by DTA, which did not show any exothermic or endothermic peaks.

Fig. 4 displays the morphology and microstructures of the combustion product. Fig. 4A is a typical SEM image of the as-prepared powder, showing aggregates of uniform size. Fig. 4B is a TEM bright field image of a typical powder particle. The aggregates in terms consists of finer nanocrystallites of size $\sim 10-20\,\mathrm{nm}$. Fig. 4C shows a selected area electron diffraction (SAED) pattern recorded at an accelerating voltage of $200\,\mathrm{kV}$, which corresponds to an electron

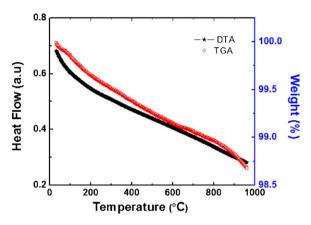

Fig. 3. DTA and TGA curves of the as-prepared Ba₂TmSbO₆.

wavelength of 2.508 pm, and at a camera length of 915 mm. The SAED pattern shows rings that can be indexed to cubic structure. The ring nature of the SAED is indicative of the polycrystalline nature of the crystallites. Fig. 4D shows a high resolution lattice image showing a grain boundary; the grain boundary was sharp and free from any impurities.

The material was sintered and had high mechanical strength. The samples could be sliced into thin discs using a diamond cutter; well polished surfaces were obtained by mechanical polishing. Fig. 5 shows the surface morphology of the sintered $\text{Ba}_2\text{TmSbO}_6$ samples showing well crystallized sub-micron grains with sharp grain boundaries. No cracks or pores were observed on the surface. Sintering increased the grain size of the as-prepared $\text{Ba}_2\text{TmSbO}_6$; average grain size determined from the SEM micrographs was $\sim\!700\,\text{nm}.$

3.2. Structural characterization of Ba₂TmSbO₆

Fig. 6 shows the FT-IR spectrum of as-prepared Ba_2TmSbO_6 powder. The asymmetric stretching and bending modes of the BO_6 octahedra of the ABO_3 unit cell usually dominate the IR spectra of perovskites [16,19]. However, from a comparative study of the vibrational patterns of phonon modes in two types ABO_3 unit cells, Sopracase et al. concluded that most of phonon modes in these types of unit cells correspond to complex atomic vibrations and significantly different from one another which cannot be assigned only to a given type of vibration, i.e., external, bending, or stretching modes [20]. The present Ba_2TmSbO_6 ($Ba_2L_nMO_6$) consists of corner-sharing SbO_6 (MO_6) and TmO_6 (L_nO_6) octahedra. The band centred at \sim 470 cm $^{-1}$ is assigned to the asymmetric bending mode ν_4 (T_{1u}) of the SbO_6 (TmO_6) octahedra. The intense band centred at \sim 620 cm $^{-1}$ is assigned to the asymmetric stretching

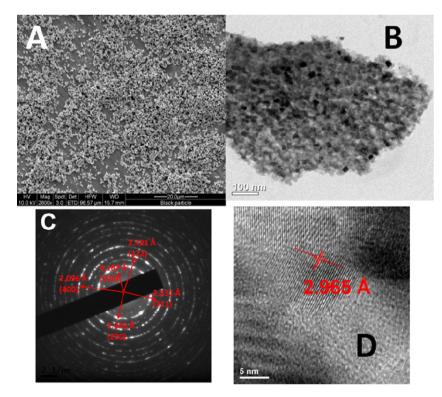

Fig. 4. (A) SEM image of the finely dispersed powder in ethanol; (B) bright field TEM image showing a typical powder particle; (C) selected area electron diffraction pattern of Ba₂TmSbO₆, the first five rings are indexed following the lattice parameter and camera constant; (D) a high resolution lattice image showing sharp grain boundary indicating the chemical purity of the material synthesized in the present work; the lattice fringe is from the (2 2 0) plane.

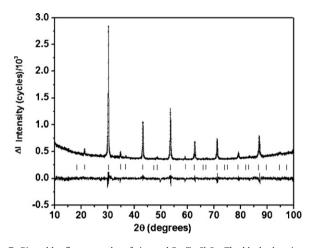

Fig. 7. Rietveld refinement plot of sintered Ba_2TmSbO_6 . The black plus signs and the continuous lines show the experimental (I_{obs}) and simulated (I_{cal}) intensities, respectively. $\Delta I = I_{cal} - I_{obs}$ below. The vertical lines indicate positions of all the Bragg reflections from the $Fm\bar{3}m$ space group with lattice parameter 8.4101 Å.

mode ν_3 (T_{1u}) of the SbO₆ (TmO₆) octahedra. All these four bands merged into a single Gaussian profile indicating the similarity of bending/stretching frequencies of the SbO₆ and TmO₆ octahedra. Similar spectral pattern with two strong and well-defined IR bands in the 400– $650\,\mathrm{cm}^{-1}$ region has been found in a number of Ba₂L_nMO₆ perovskite type materials [21–24]. The weak band centred at $1053\,\mathrm{cm}^{-1}$ is assigned to the symmetric stretching mode ν_1 (A_{1g}) of SbO₆ (TmO₆) octahedra. The broad band centred at $1430\,\mathrm{cm}^{-1}$ arises from water vapour adsorbed due to ultrafine particle size of the combustion product. Similarity in the asymmetric and symmetric bending frequencies indicates that a symmetry lowering from cubic has not taken place in Ba₂TmSbO₆. We also note that the above observations corroborate the XRD and thermal analyses results that the combustion is complete and no organic matter present in the as-obtained combustion product.

Structure of the sintered Ba_2TmSbO_6 was studied by Rietveld analysis of X-ray diffraction measurements. Fig. 7 shows XRD patterns of the Ba_2TmSbO_6 and refined using the PowderCell 2.3 program [25]. Residues of fitting were R_{WP} = 4.13, R_P = 3.12, R_e = 3.13, where the symbols have their usual meanings [25]. The goodness of fit indicator, $S = R_{WP}/R_e$, was 1.32, which represents a good fit. The lattice parameter of the sintered Ba_2TmSbO_6 was 8.4101 Å, very similar to that calculated from the XRD pattern of the as-prepared nanocrystals. All the peaks in the XRD pattern fit

well to cubic perovskite with space group $Fm\bar{3}m$ (No. 225). This space group allows two crystallographically distinct octahedral sites in Ba₂TmSbO₆ material, thus permitting the 1:1 positional ordering between B-site Tm³⁺ ions and Sb⁵⁺ ions. The ions are arranging alternatively and have a rocksalt sublattice. The alternative arrangement of Tm³⁺ and Sb⁵⁺ ions results in a superstructure. The Sb and L_n cations arrange randomly in equivalent positions of the crystal structure in a substitutional solid solution. If upon suitable heat treatment the random solid solution rearranges into a structure in which the Sb and L_n cations occupy the same set of positions but in a regular way, the structure is described as a superstructure. Presence of (odd, odd, odd) reflections such as (311) and (511) in the XRD patterns indicate the formation of the superstructure which lead to multiplication of the basic perovskite unit cell. Note that these reflections are also used to characterize the antiphase tilting occurs when 0.964 < t < 0.985 [26]. However, t of the Ba₂TmSbO₆ is 0.992 which is expected to be an untilted system. as clearly demonstrated by the IR and XRD studies: and therefore. those reflections denote the superstructural doubling of the basic perovskite unit cell. Volume of the cell calculated from the cell parameters was 594.844 Å³. The theoretical density of Ba₂TmSbO₆ calculated from the cell volume and masses of the atoms composing the unit cell was 7.340 g/cm³. Sintered density of Ba₂TmSbO₆ was 7.08 g/cm³; which was about \sim 97% of the theoretical density calculated from the XRD analysis.

To check whether any symmetry lowering than $Fm\bar{3}m$ was occurred in Ba₂TmSbO₆, the observed XRD pattern was fitted to the monoclinic $P2_1/n$ space group using the structural model described before [8]. Although the pattern fits well to the $P2_1/n$ space group also the residues were much higher than that of the $Fm\bar{3}m$ (S over 1.5). Therefore, within the limitations of the present experiment as well as predicted by Fig. 1, we conclude that Ba₂TmSbO₆ adopts cubic structure.

3.3. Dielectric properties of Ba₂TmSbO₆

The new material is an insulator with resistivity \sim 5 M Ω /cm. The dielectric constant (ε_r) and loss factor (tan δ) of the new material were studied from capacitance measurements by sandwiching the sintered specimen between two silver electrodes. Fig. 8A shows the variation of $\varepsilon_{\rm r}$ and $\tan \delta$ as a function of frequency of the new material. The Ba₂TmSbO₆ has a ε_r of 17 and tan δ of 10⁻⁴ at 5 MHz and at room temperature. The dielectric constant of a material can be calculated using the molar volume $(V_{\rm m})$ and total dielectric polarizability (α_D) using the equation $\varepsilon_r = ((3V_m + 8\pi\alpha)/3V_m - 4\pi\alpha)$. By using the dielectric polarizabilities reported by Shannon [27], we arrive at $\varepsilon_r \sim 15.98$, which closely matches with the experimental value. The ε_r of the Ba₂TmSbO₆ was in a range reported for the other Ba₂L_nSbO₆ (Fig. 8B) compiled from published literature [9]. The dielectric constant of the new material is in the medium range among the other Ba₂L_nSbO₆ perovskites. However, the measured dielectric loss, i.e., $\tan\delta$, of the nanocrystalline Ba_2TmSbO_6 is the lowest among them. The $\tan \delta$ generally increases with increase in ε' , which arise from dielectric polarization. A possible source of discrepancy is the method of synthesis between the other rare-earth barium antimonates, whose microcrystals with lesser chemical purity were synthesized by the solid state reaction of oxides and/or carbonates. On the other hand, the present Ba₂TmSbO₆ is nanocrystalline with superior chemical purity due to atomic level mixing of the ions forming the compound. The lower value of $\tan \delta$ for a higher ε' is thus expected to arise from the chemical purity as well as submicron sized grains in the sintered product. The lower $\tan \delta$ of the new material is beneficial to fabricate low-loss microwave electronic circuits.

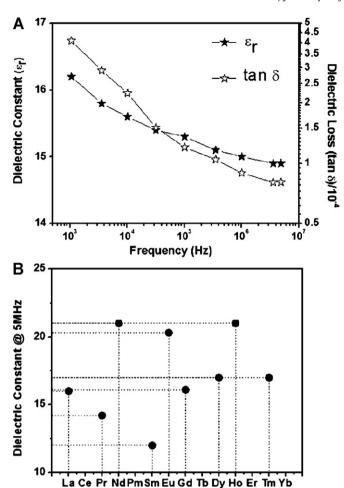

Fig. 8. (A) Dielectric constant and loss factor of Ba₂TmSbO₆ determined from the capacitance measurements and (B) the dielectric constant of sintered $Ba_2L_nSbO_6$ determined from the published literature.

Ln in Ba2LnSbO6

4. Conclusions

In conclusion, a new material Ba₂TmSbO₆ has been synthesized as single phase nanoparticles of average size 30 nm using a combustion process. X-ray diffraction and electron diffraction have shown that the as-prepared powder is single phase Ba₂TmSbO₆ and has a complex perovskite structure with lattice constant a = 8.4101 Å. The nanocrystalline Ba₂TmSbO₆ was sintered to ~97% of its theoretical density at 1450°C for 4h with well faceted cuboidal morphology. The Ba2TmSbO6 is an insulator (resistivity \sim 5 M Ω /cm) and has dielectric constant (ε ') and dielectric loss $(\tan \delta)$ of \sim 17 and \sim 10⁻⁴ at 5 MHz, respectively. The new material was featured by a lowest dielectric loss among the other barium rare-earth antimonates.
